

# *AWS IAM Policy Simulator & Best Practices + STS & Role Assumption*

Duration: 60 min | Level: Intermediate

This presentation covers two essential AWS security topics: the IAM Policy Simulator for testing and debugging permissions, and STS for secure cross-account access. We'll explore best practices for both to help you implement robust security controls in your AWS environment.

## *Part 1*

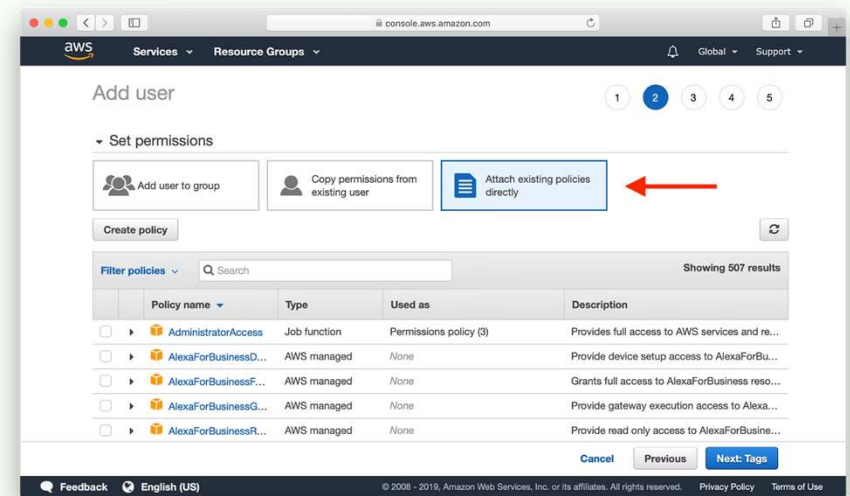

### *IAM Policy Simulator & Best Practices*

# *Introduction to IAM Policy Simulator*

The **AWS IAM Policy Simulator** is a service designed to test IAM and resource-based policies before applying them to your production environment.

This powerful tool helps you:

- Validate permissions before applying them
- Reduce trial-and-error in production environments
- Debug frustrating "AccessDenied" issues

Access the simulator at: <https://policysim.aws.amazon.com>

# *Key Features of Policy Simulator*

## ***Comprehensive Policy Testing***

Evaluate IAM policies, Service Control Policies (SCPs), and resource-based policies in a safe environment

## ***Entity Coverage***

Test permissions for users, groups, and roles to ensure proper access control

## ***API Simulation***

Simulate specific API calls to verify if they would be allowed or denied

## ***Clear Results***

View detailed allow/deny results with explanations of which policy statements affected the decision

## ***Multi-Service Support***

Test permissions across multiple AWS services from a single interface

# *How to Use IAM Policy Simulator*

## Demo Workflow

### **1** *Open Policy Simulator*

Access the simulator through the AWS Console or directly at [policysim.aws.amazon.com](https://policysim.aws.amazon.com)

### **2** *Select Identity*

Choose the User, Group, or Role whose permissions you want to test

### **3** *Choose Service*

Select the AWS service you want to test (e.g., S3, EC2, DynamoDB)

### **4** *Select Actions*

Choose specific API actions to test (e.g., `s3:ListBucket`, `ec2:DescribeInstances`)

### **5** *Run Simulation*

Execute the test and check results (Allow/Deny + detailed explanation)

### **6** *Iterate*

Modify the policy and re-simulate until you achieve the desired permissions

# Common Use Cases

## *Debugging Permission Issues*

Quickly identify why a user is receiving "AccessDenied" errors without modifying production policies

## *Testing New Policies*

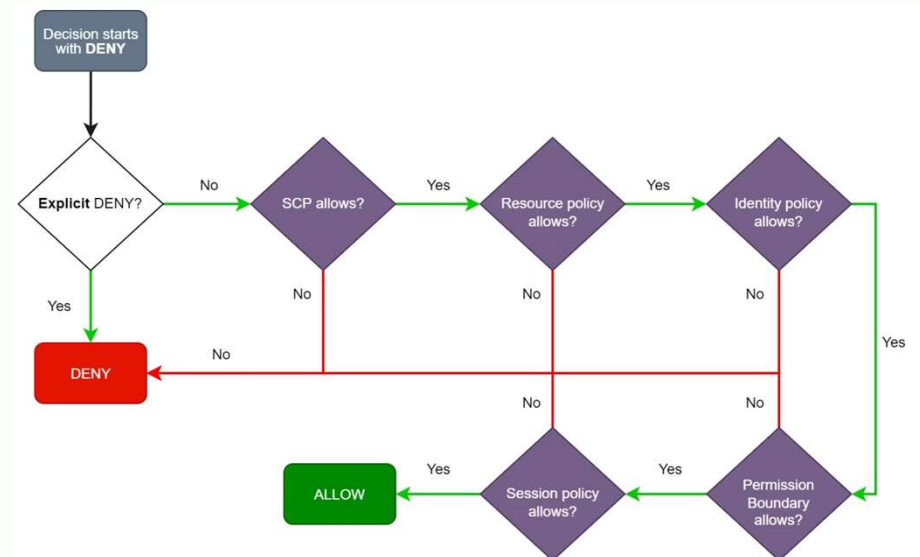

Validate new or updated policies before deployment to prevent accidental permission gaps or excessive access

## *Validating SCP Impacts*

Understand how Service Control Policies in AWS Organizations affect permissions across your organization

## *Reviewing Third-Party Permissions*

Verify the actual permissions granted to third-party roles before allowing them access to your resources

# *IAM Best Practices: Security & Management*

## ***Least Privilege Principle***

Grant only the permissions required to perform a task - nothing more

## ***Use Roles Instead of Keys***

Prefer temporary role credentials over long-term access keys

## ***Enable MFA***

Require multi-factor authentication for all privileged accounts

## ***Use IAM Groups***

Assign permissions to groups rather than individual users

## ***Rotate Access Keys***

Regularly rotate access keys to minimize risk from compromised credentials

## ***Implement SCPs***

Use Service Control Policies for organization-level permission guardrails

## ***Enable Logging***

Log all IAM changes via CloudTrail for comprehensive audit trails

# *IAM Best Practices: Policy Management*

- Use **AWS Managed Policies** when possible for standardized permission sets
- **Restrict wildcard (\*) actions** to prevent unintended access
- **Apply Conditions** to limit when policies are effective:
  - aws:SourceIp - restrict by IP address
  - aws:MultiFactorAuthPresent - require MFA
- **Use tags** for attribute-based access control (ABAC)
- **Version control** your IAM policies via Infrastructure as Code (Terraform/CloudFormation)

## IAM policy structure

```
{  
  "Statement": [{  
    "Effect": "effect",  
    "Principal": "principal",  
    "Action": "action",  
    "Resource": "arn",  
    "Condition": {  
      "condition": {  
        "key": "value" }  
      }  
    }  
  ]  
}
```

**P**incipal – The entity that is allowed or denied access

"Principal": "AWS": "arn:aws:iam::123456789012:user/username"

**A**ction – Type of access that is allowed or denied access

"Action": "s3:GetObject"

**R**esource – The Amazon resource(s) the action will act on

"Resource": "arn:aws:sqs:us-west-2:123456789012:queue1"

**C**ondition – The conditions under the access defined is valid

"StringEqualsIfExists": {"aws:RequestTag/project": ["Pickles"]}

# Quick Demo Idea

5 minutes

## ***Problem***

User receives "AccessDenied" when attempting to delete an S3 object

## ***Investigate***

Use Policy Simulator to test s3:DeleteObject permission and identify the missing permission

## ***Fix***

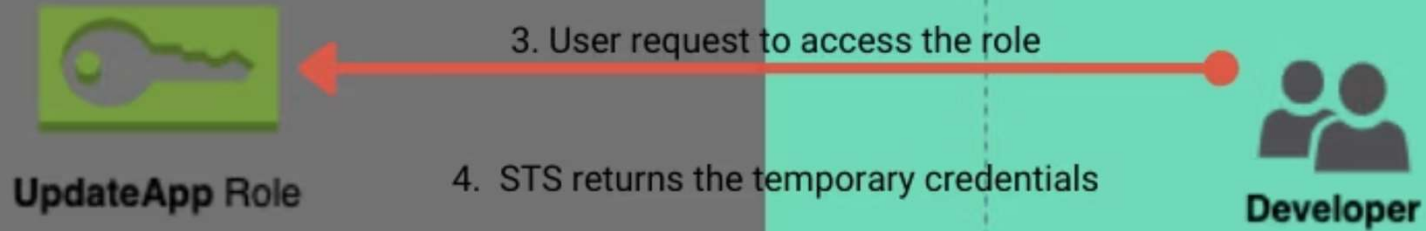

Update the IAM policy to include the necessary permission

## ***Verify***

Re-test in Policy Simulator to confirm the fix works before applying to production

## *Part 2*

### *STS & Role Assumption*

Cross-Account Basics (~30 min)

# Introduction to AWS STS

AWS Security Token Service (STS) is a global web service that issues temporary security credentials for accessing AWS resources.

## Why Use STS?

- **Cross-account access** - Access resources in different AWS accounts
- **Federated identity** - Integrate with external identity providers (Active Directory, Google, etc.)
- **Temporary privilege escalation** - Grant elevated permissions only when needed

 STS credentials are temporary by design, enhancing security by limiting the exposure window if credentials are compromised.

# *Key STS API Calls*

## ***AssumeRole***

Switch to a different IAM role within your account or in another AWS account

```
aws sts assume-role --role-arn ROLE_ARN --role-session-name SESSION_NAME
```

## ***GetSessionToken***

Get temporary credentials for an IAM user or AWS account root user, typically used with MFA

```
aws sts get-session-token --serial-number MFA_DEVICE --token-code TOKEN
```

## ***AssumeRoleWithSAML***

Returns temporary credentials for users authenticated with SAML-based federation

```
aws sts assume-role-with-saml --role-arn ROLE_ARN --principal-arn PRINCIPAL_ARN --saml-assertion SAML_ASSERTION
```

## ***AssumeRoleWithWebIdentity***

Returns temporary credentials for users authenticated with an OpenID Connect (OIDC) provider

```
aws sts assume-role-with-web-identity --role-arn ROLE_ARN --web-identity-token TOKEN
```

# Role Assumption Basics

## Role

A set of permissions that AWS can assign to an authenticated entity

## Trust Policy

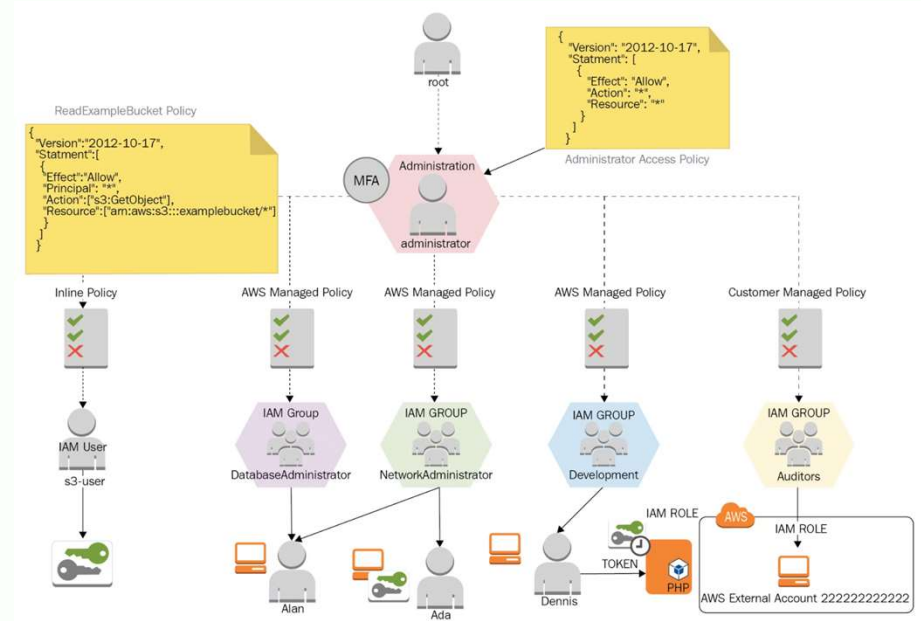

Defines who can assume the role (the trusted entities)

## Permission Policy

Defines what actions the role can perform on which resources

## Session Duration

15 minutes to 12 hours (default: 1 hour)

Roles are the foundation of temporary access in AWS. They separate *who* can access resources (trust policy) from *what* they can do (permission policy).

## *Cross-Account Access Flow*

### *Account A (Resource Owner)*

- Create IAM Role with trust policy for Account B
- Attach permission policy defining allowed actions

### *Account B (User Account)*

- Use STS AssumeRole to get temporary credentials
- Access Account A's resources using these credentials

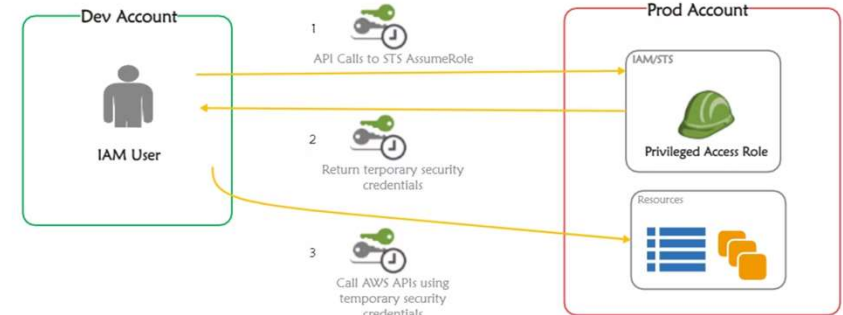

## Example: Assume Role CLI Command

```
aws sts assume-role --role-arn
arn:aws:iam::111122223333:role/CrossAccountS3Access --
role-session-name MySession
```

The command returns temporary credentials:

- Access Key ID
- Secret Access Key
- Session Token

These credentials can be used with any AWS SDK or CLI by setting the appropriate environment variables or profile configuration.

- ❏ The role-session-name parameter helps identify who assumed the role in CloudTrail logs, aiding in security auditing.

# *Security Best Practices for STS*

## ***Use Short Session Durations***

Limit session duration to the minimum time needed to complete tasks, reducing the window of opportunity if credentials are compromised

## ***Require MFA for Role Assumption***

Add the `aws:MultiFactorAuthPresent` condition to trust policies for sensitive roles

## ***Limit Trusted Principals***

Be specific about which entities can assume roles; avoid wildcards in trust policies

## ***Log AssumeRole Events***

Monitor CloudTrail for suspicious role assumption patterns or unauthorized attempts

## ***Avoid Using STS for Permanent Access***

Don't script continuous role assumption as a workaround for proper cross-account access design

# Demo Idea

10 minutes

## Setup:

1. Create Role in Account A with S3 read permissions
2. Configure trust policy to allow Account B's user to assume the role
3. From Account B, assume the role using STS
4. List S3 objects in Account A using the temporary credentials
